1. Trump administration: tariffs to target the trade balance.

   1. A stupid target
   2. Is there logic to the mechanism?
   3. Now and also back when: "A typical argument for protectionist legislation emphasizes two supposed results from higher tariffs. First, by making foreign goods more expensive, tariffs cause imports to fall and thus improve the current account. Second, as domestic residents shift expenditure patterns from foreign to domestic goods, home employment and production are stimulated. Fewer Americans driving Toyotas and BMW’s mean more jobs for blast furnace operators in Gary, for tire producers in Akron, and for assembly line workers in Flint." — Aschauer (1987).
1. But identities:

\[
S(W?) - I(r?) = CAS(TT?) = \Delta NFA;
\]

\[W \text{ for wealth, } TT : \text{ terms of trade; } r : i - \text{rate}\]

2. Tariffs have direct effect on CAS, not (obvious) on \(S, I\).

3. Needed: a model to disentangle

4. Thought experiment: change tariffs, see what happens in GE
Intro: what happened?

Trump: essentially imposed tariffs across the entire spectrum of sectors comprising Chinese imports, representing a seismic increase in the value of trade affected and the scope of sectors drawn into the tariff catchment.

Intro: Prices and quantities

2. We collect a time series for the purposes of estimating the following structural vector autoregression (sVar) model:

\[
B_0 y_t = c + \sum_{j=1}^{p} B_{1j} y_{t-j} + \varepsilon_t;
\]

\[
y_t : [T_i^C, TT_i^W, S_t^d, Inv^d_t, TB_t^C]
\]

where \(T_i^C\) is tariff revenue from Chinese imports, \(TT_i^W\) is US terms of trade vis a vis the world, \(S_t^d\) is real US domestic sales, \(Inv^d_t\) is real inventories of US producers, and \(TB_t^C\) is the real bilateral trade balance surplus between US and China.

3. Salient results: estimated impulse response functions show—among other things—sharp initial \(TT\) appreciation, followed by depreciation, negligible effect on \(TB_t^C\).
Other models could be used, e.g., Chari, Kehoe, McGratten (1999).

For this purpose, we want a model in which

1. Savings behavior not directly–behaviorally– affected by tariff; trade balance not directly affected by variables that affect savings behavior.
2. There is a steady state, with unique level of net indebtedness.
3. Include capital flows.

Hence, a variant of continuous-time OLG (Buiter)
Heterogeneity: savers and non-savers
Heterogeneity: savers and non-savers
- Simplifies dynamics
Heterogeneity: savers and non-savers

- Simplifies dynamics
- Allows nesting of traditional long-run model
Heterogeneity: savers and non-savers

- Simplifies dynamics
- Allows nesting of traditional long-run model
- Allows parametric solution in which non-savers get all of tariff revenue: savings unaffected
Heterogeneity: savers and non-savers

- Simplifies dynamics
- Allows nesting of traditional long-run model
- Allows parametric solution in which non-savers get all of tariff revenue: savings unaffected

OLG a la Blanchard and Buiter
**Framework**

**Strategy**

- **Heterogeneity:** savers and non-savers
  - Simplifies dynamics
  - Allows nesting of traditional long-run model
  - Allows parametric solution in which non-savers get all of tariff revenue: savings unaffected

- **OLG a la Blanchard and Buiter**
  - Permits analysis of long-run net indebtedness
Heterogeneity: savers and non-savers
- Simplifies dynamics
- Allows nesting of traditional long-run model
- Allows parametric solution in which non-savers get all of tariff revenue: savings unaffected

OLG a la Blanchard and Buiter
- Permits analysis of long-run net indebtedness
- More tractable than other approaches, e.g., Daniels.
There are only two countries, home (also described as the domestic country) and foreign. Variables associated with the foreign country will be distinguished from home-country variables by having a "star" (*) attached as a superscript.
There are only two countries, home (also described as the domestic country) and foreign. Variables associated with the foreign country will be distinguished from home-country variables by having a "star" (\( * \)) attached as a superscript.

Two goods are produced in each country. In the home country, a non-traded good, denoted by \( N \), and an exported good, denoted by \( X \), are produced. In the foreign country, a non-traded good, denoted by \( N^* \), and an exported good, denoted by \( M \), are produced.

- Two goods are produced in each country. In the home country, a non-traded good, denoted by $N$, and an exported good, denoted by $X$, are produced. In the foreign country, a non-traded good, denoted by $N^*$, and an exported good, denoted by $M$, are produced.

- Residents of each country are of two types:
  - Impatient types, who do not save or borrow.
  - Patient types, who optimize intertemporally, but who only get income from work in the non-traded sector and only consume the non-traded good.

- The home country residents consume the non-traded good and the good exported from the foreign country, $M$. They do not consume the good produced at home and exported to the foreign country, $X$. 
1. Consider a model with three goods, an importable, an exportable, and a non-traded good. The importable is not produced domestically, and the exportable is not consumed domestically. The economy has at least three factors of production, one of which is labor. These factors of production are supplied inelastically and full employment prevails. Write down the system of equations that determines the following endogenous variables: the wage rate, the price of non-tradables, and welfare.

2. For a small open economy, the real exchange rate is defined as the inverse of the relative price of home goods to tradables. In our model, two potential indicators of the real exchange rate are the price of the non-traded good...
Relative prices:

\[ \pi_x \equiv \frac{P_X}{P_N}, \quad \pi_m \equiv \frac{P_M}{P_N}; \quad \pi^*_x \equiv \frac{P^*_X}{P^*_N}, \quad \pi^*_m \equiv \frac{P^*_M}{P^*_N}. \]

Big Mac exchange rate (a real rate):

\[ e \equiv \frac{EP^*_N}{P^*_N}, \]

where \( E \) is the domestic currency price of foreign currency.
Supply

\[ X^s = \chi \left( \frac{P_X}{P_N} \right); \]

\[ M^s = \mu^* \left( \frac{P_M^*}{P_N^*} \right); \]

\[ N^s = \nu \left( \frac{P_X}{P_N} \right); \quad N^{*,s} = \nu^* \left( \frac{P_M^*}{P_N^*} \right); \]
Preferences of representative "impatient" individual:

\[ U = N + \left( \frac{\gamma}{\theta} \right) M^{\theta}; \quad \gamma > 0, \; \theta < 1. \]
Demand by the impatient people

- Preferences of representative "impatient" individual:

\[ U = N + \left( \frac{\gamma}{\theta} \right) M^{\theta}; \gamma > 0, \theta < 1. \]

- Budget constraint:

\[ \frac{Y}{P_N} = N - \frac{P_M}{P_N} M \]
Demand by the impatient people

- Preferences of representative "impatient" individual:
  \[ U = N + \left( \frac{\gamma}{\theta} \right) M^\theta; \quad \gamma > 0, \theta < 1. \]

- Budget constraint:
  \[ \frac{Y}{P_N} = N - \frac{P_M}{P_N} M \]

- Income \( Y \) includes profits from the \( X \) industry, and any transfers of tariff revenue from the govt.
Demand by the impatient people

- Preferences of representative "impatient" individual:

\[ U = N + \left( \frac{\gamma}{\theta} \right) M^\theta; \gamma > 0, \theta < 1. \]

- Budget constraint:

\[ \frac{Y}{P_N} = N - \frac{P_M}{P_N} M \]

- Income \( Y \) includes profits form the \( X \) industry, and any transfers of tariff revenue from the govt.

Hence, the demands for the traded goods are:

\[ M^d = \mu(\pi_m); \]

\[ X^d = \chi^*(\pi_x^*); \]
Equilibrium in traded-goods markets

- Law of one price:

\[
P_M (1 - t) = E P^*_M; \\
P_X = E P^*_X.
\]
Law of one price:

\[ P_M (1 - t) = EP^*_M; \]
\[ P_X = EP^*_X. \]

Can write relative prices traded vis a vis non-traded as

\[ \frac{P_M}{P_N} = \frac{EP^*_M}{(1 - t) P_N} \times \frac{P^*_N}{P^*_N} = \left( \frac{EP^*_N}{P_N} \times \frac{1}{1 - t} \right) \times \frac{P^*_M}{P^*_N}; \]
\[ \pi_m = \left( \frac{e}{1 - t} \right) \pi^*_m; \]
\[ \frac{P_X}{P_N} = \frac{EP^*_X}{P_N} \times \frac{P^*_N}{P^*_N} = \left( \frac{EP^*_N}{P_N} \right) \times \frac{P^*_X}{P^*_N}; \]
\[ \pi_X = e \pi^*_X. \]
Equilibrium in traded goods markets

Equating demand to supply in the markets for $M$ and $X$, we can solve for the equilibrium prices and quantities as functions of $e$ and $t$:

\[
\begin{align*}
\hat{\pi}_m^* &= \pi_m^*(\frac{e}{1-t}); \\
\hat{\pi}_m &= \pi_m(\frac{e}{1-t}); \\
\hat{M}^d &= M\left(\frac{e}{1-t}\right).
\end{align*}
\]

\[
\begin{align*}
\hat{\pi}_x^* &= \pi_x^*(e); \\
\hat{\pi}_x &= \pi_x(e); \\
\hat{X}^s &= X(e).
\end{align*}
\]
Thus, as a function of $e$, we have the following expression for the trade surplus along with associated derivatives:

$$\begin{align*}
T &= C_x e^{\frac{k_x^d(1+k_x^s)}{k_x^s + k_x^d}} - D_m (e) \frac{k_m^s(1-k_m^d)}{k_m^s + k_m^d} (1 - t) \frac{k_m^d(1+k_m^s)}{k_m^s + k_m^d}; \\
C_x &\equiv (A_x^s) \frac{k_x^d - 1}{k_x^s + k_x^d} (A_x^d); \quad D_m \equiv (A_m^d) \frac{1+k_m^s}{k_m^s + k_m^d} (A_m^s) \frac{k_m^d - 1}{k_m^s + k_m^d} \\
\frac{\partial T}{\partial e} &= k_x^d \frac{1 + k_x^s}{k_x^s + k_x^d} \left( C_x e^{\frac{k_x^s(k_x^d - 1)}{k_x^s + k_x^d}} \right) - \frac{k_m^s(1-k_m^d)}{k_m^s + k_m^d} \left( D_m (e) \frac{-k_m^d(k_m^s+1)}{k_m^s + k_m^d} (1 - t) \frac{k_m^d - 1}{k_m^s + k_m^d} \right) \quad (1 - \\
\frac{\partial T}{\partial t} &= \left( \frac{k_m^d(1+k_m^s)}{k_m^s + k_m^d} \right) D_m (e) \frac{k_m^s(1-k_m^d)}{k_m^s + k_m^d} (1 - t) \frac{k_m^d - 1}{k_m^s + k_m^d} > 0 .
\end{align*}$$
Lagniappe!
As an aside, we note that this development of the trade balance, in which the elasticities \( k_i^j \) play such a prominent role, is much like what was emphasized in the "elasticities approach" to the balance of trade. We also note that in our model the condition for \( \frac{\partial T}{\partial e} > 0 \) is the same as the so-called Bickerdike-Robinson-Metzler expression:

\[
\left( \frac{k_x^d (1 + k_x^s)}{k_x^s + k_x^d} - \frac{k_m^s (1 - k_m^d)}{k_m^s + k_m^d} \right) > 0.
\]

It is straightforward to show that a sufficient condition for this to be satisfied is the perhaps better known Marshall-Lerner condition:

\[
1 - k_m^d - k_x^d < 0.
\]
Savers

- OLG with constant death probability $\theta$ and constant time preference $\rho$. 

Instantaneous utility given by $U = \ln N$. 

People can borrow and lend abroad at $r$ or at home at $r$. 

Frank Ciarliero, Richard Cantor, and Robert [ ]

Thanks Trump!

Savers demand for home good

\[ N^D_S = (\theta + \rho) W \]  

where

\[ W = -F + H; \]

\[ H = \frac{[\bar{L}_S (\beta_N + \tau)]}{R + \theta}, \]

\[ \frac{1}{R} = \int_{v=t}^{\mu=\nu} \exp\left(-\int_{v=t}^{\mu=\nu} r(\mu) d\mu\right) d\nu. \]

- \( F \) is net foreign indebtedness measured in units of domestic non-traded goods, and is equal to \( f + ef^* \).
- \( H \) is human wealth, the PDV of lifetime income flows; \( \bar{L}_S \) is measure of population that are savers, \( \beta_N \) is the (constant) \( MPL_N \), and \( \tau \) is the per capita government transfer (which comes as a fraction \((1 - \Gamma)\) of tariff revenue).
All bonds, i.e., long, short, domestic, and foreign, are perfect substitutes.
Asset arbitrage

- All bonds, i.e., long, short, domestic, and foreign, are perfect substitutes.
- Implication:

  \[ r \approx r^* + \dot{e}; \]

  \[ \frac{\dot{R}}{R} = R - r. \]
Market for non-traded goods

Supply is a decreasing function of $e$:

$$N^s = N^s(e).$$

Demand by non-savers: an increasing function of $e$ and of $\Gamma$.

$$N^d_{NS} = N^d_{NS} \left( e, \Gamma \right).$$

Demand by savers is

$$N^d_S = N^d_S \left( t, \Gamma, R \right).$$

Equilibrium:

$$R = \chi(e, t, \Gamma)$$
Changes in net national indebtedness equal minus the current account:

$$\dot{F} = rF - T(e).$$
The balance of payments constraint

- Changes in net national indebtedness equal minus the current account:
  \[ \dot{F} = rF - T(e). \]

- Note: a long-run RER theory found by setting \( \dot{F} = 0. \)
Changes in net national indebtedness equal minus the current account:

\[ \dot{F} = rF - T(e). \]

Note: a long-run RER theory found by setting \( \dot{F} = 0 \).

Niehan's "static deviations from PPP."
Changes in net national indebtedness equal minus the current account:

\[ \dot{F} = rF - T(e). \]

Note: a long-run RER theory found by setting \( \dot{F} = 0 \).

- Niehan’s "static deviations from PPP."
- Question answered here (and in Buiter): How to determine long-run \( F \) (and \( e \)) in optimizing model.
Solution

Steady state

Proposition

If the home country is characterized vis a vis the foreign country by a rate of time preference greater than the exogenous foreign-country rate of interest, i.e., is characterized by $\rho > r^*$, then the home country in the steady state is a net borrower, i.e., $F > 0$.

Proposition

If the home country is characterized vis a vis the foreign country by a rate of time preference less than the exogenous foreign-country rate of interest, i.e., is characterized by $\rho < r^*$, and if $(r^* - \theta - \rho) < 0$, then the home country in the steady state is a net lender, i.e., $F < 0$. 
Steady state solution: example

\[ k_i^j = 1, A_i^j = 1 \]

\[ \Gamma = .5, \quad t = 0, .1, \quad \rho = .1, \quad r^* = R = \theta = .05; \]
\[ r^* - \rho = -.05, \quad R + \theta = .1; \]
\[ \bar{L}_S = 1, \quad \bar{L}_{NS} = 1, \quad \beta_N = \frac{1}{2}. \]

Solution:

1. \( t = 0 \):

\[ \bar{e} = 1.125; \quad \bar{F} = 2.5; \quad T = .125. \]

2. \( t = .1 \):

\[ \bar{e} = 1.0375; \quad \bar{F} = .275; \quad T = 0.1375. \]

The imposition of the tariff has increased net indebtedness and appreciated the currency. The trade balance surplus is bigger as it must be to pay for the increased net factor payments to the foreign country.
Coupled differential equations, linearized around steady state:

\[
\dot{e} = a_{11} e - a_{11} \bar{e}; \\
\dot{F} = a_{21} e + a_{22} F - a_{21} \bar{e} - a_{22} \bar{F},
\]

where

\[
e \left( (\chi_e) (r^*) + \chi_F \frac{\partial T}{\partial e} \right) \\
\frac{(e\chi_e + \chi_F F + \chi)}{(e\chi_e + \chi_F F + \chi)} \equiv a_{11};
\]

\[
F\chi_e r^* - e\chi_e \frac{\partial T}{\partial e} - \chi \frac{\partial T}{\partial e} \\
\frac{(e\chi_e + \chi_F F + \chi)}{(e\chi_e + \chi_F F + \chi)} \equiv a_{21};
\]

\[
r^* = a_{22}.
\]

All expressions in (14) are evaluated at their steady-state values. The key simplification in the model that makes (13a) independent of $F$ is the assumption that savers only consume the non-traded good.
For a net debtor country (we argue this is the case for the US despite some controversies over this):

1. Tariffs are predicted by our (special) model to have small effects on the trade balance, and the data supports this (both imports and exports fall).
2. Tariffs lead to sharp immediate appreciation of the real exchange rate, followed by a slow depreciation (the behavior of the terms of trade suggest this is the response).
