hamster ovary cells — glycosylation is an especially complex posttranslational modification and therefore a suitable candidate for testing this approach to dynamic in vivo imaging. They incubated the cells with difluorinated cyclooctyne (DIFO) conjugated with Alexa Fluor 488 and then visualized them using a Zeiss epifluorescence microscope for various time spans and concentrations. The measurements showed that the process is imaged readily with the copper-free click chemistry technique.

The team is looking forward to applying the technique to the imaging of carbohydrates, Baskin said. They intend to explore the patterns of carbohydrates on cell surfaces, particularly in models of embryonic development and cancer. They are planning also to measure intracellular trafficking using the method.

Research probes physical mechanics of laser energy in living tissue

Scientists have unanswered questions about the physical mechanisms that occur when laser energy cuts living tissue. That has not kept lasers out of surgery, but now research at Vanderbilt University in Nashville, Tenn., is shedding light on the dynamics of laser-generated plasma in fruit fly tissue. M. Shane Hutson, the project’s lead researcher, said the work has led him to a greater appreciation of the role that a variety of molecules in tissue may play in the process.

“The overwhelming majority of previous research focused on simpler model systems,” he said. He explained that living systems often have many uncontrolled variables that make such fundamental research extremely difficult. He and postdoctoral fellow Xiaoyan Ma studied how a short pulse of 355 nm light creates a plasma and a subsequent shock wave in the tissue of fruit fly embryos.

When a laser pulse of sufficient strength strikes the tissue, it knocks free some of the electrons from atoms in the tissue. The “quasi-free” electrons quickly rejoin their atoms, which heats up the tissue and vaporizes nearby water. The vapor rapidly expands outward as a cavitation bubble, creating a series of shock waves that can be detected. Hutson said the process is interesting for two key reasons: The cavitation bubble causes tissue damage, and the shock wave formation can be used to understand the laser energy threshold needed to create the plasma.

In a series of experiments using a Continuum Q switched Nd:YAG laser delivering nanosecond pulses at 532 or at 355 nm, Hutson and Ma determined the differences in the energy threshold for both distilled water and fruit fly embryo tissue. They detected a shock wave within a few microns of a laser pulse.

Plasma formation takes place in two stages. At first, the laser must be strong enough to generate a few quasi-free seed electrons in the focal spot. Then, as the seed electrons absorb laser energy, they drive “a cascade of ionizations” that forms the full plasma. In water, the seed electrons come from a multiphoton ionization. In the fruit fly tissue, the seed electrons most likely come from a two-photon ionization of molecules such as arginine dimethylamine dihydrochloride (ADH), which requires much less energy. Hutson and Ma also determined that the size of the cavitation bubble that the 355 nm laser creates is much smaller in living tissue than in pure water.

Because ADH is a ubiquitous molecule central to biological metabolism, the research is applicable to a wide range of tissues. Hutson explained. In fact, ADH concentrations vary greatly between metabolically active tissue and tissue excited and stored for even a few hours.

Hutson said they intend to continue the investigation in three main areas — to explore laser micromachining as a way to understand developing embryos, to explore how laser parameters such as pulsewidth, affect plasma generation, and to look further into how the levels of ADH affect plasma formation.

“Our research shows that the performance of this wavelength is very different in living tissue and in those that do not contain a lot of ADH. In light of this, we have re-examined whether surgical applications of the 355-nm laser were prematurely written off.”
